

Stroke Prediction Model

Alex Re

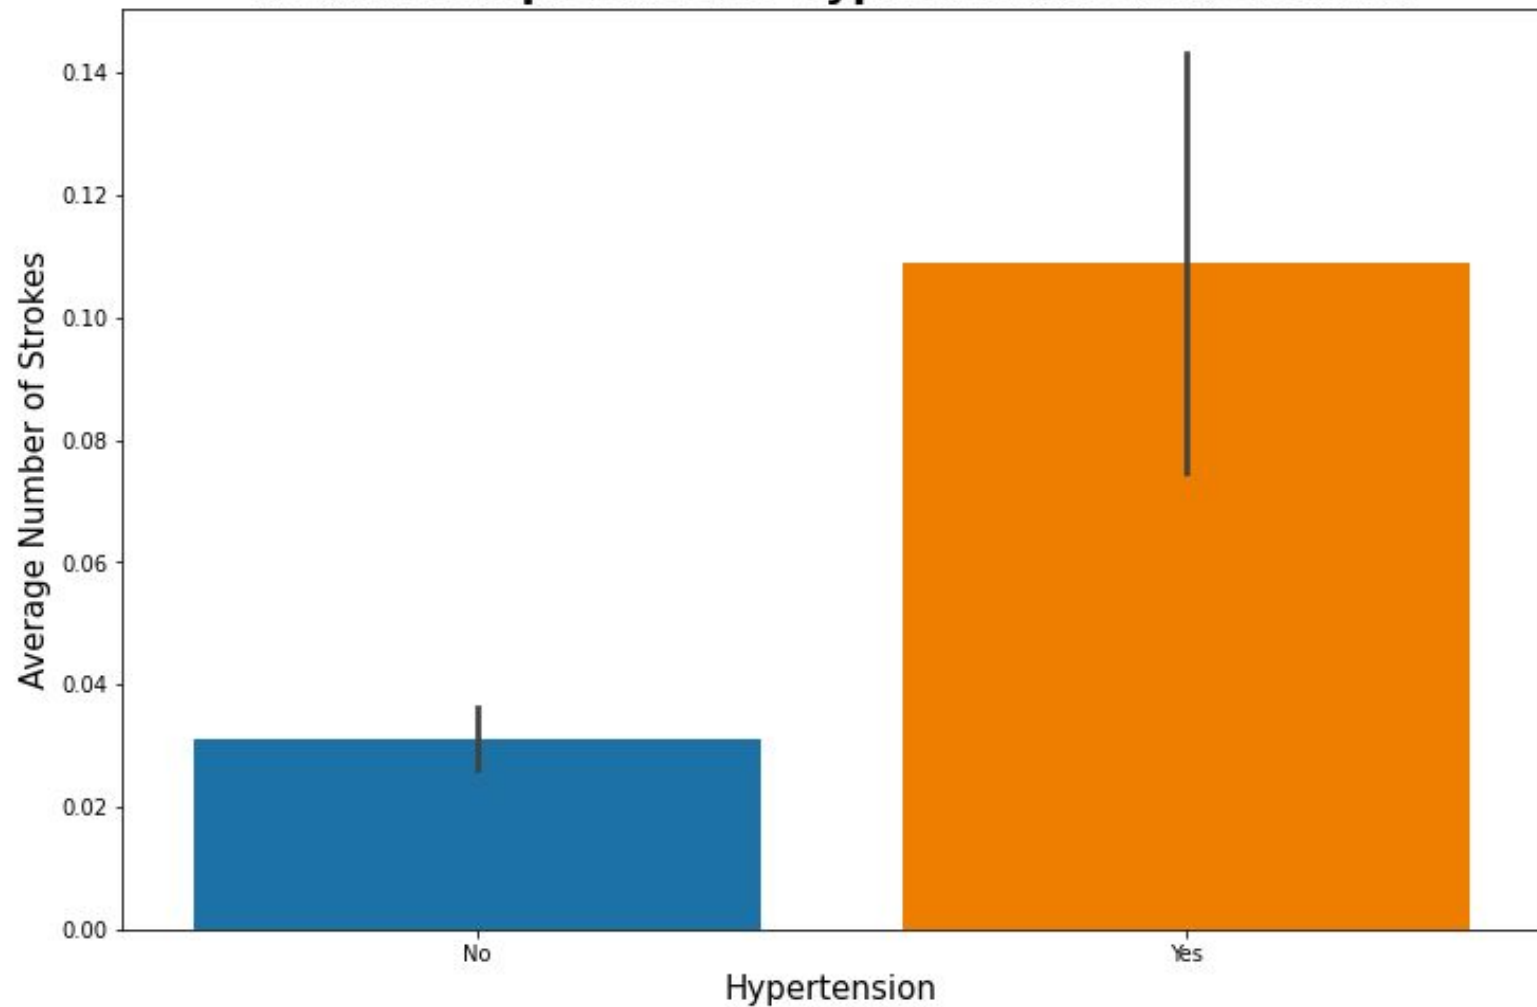

About the Dataset

- Stakeholders: Doctors of patients at risk of having a stroke
- Purpose: Using characteristics of patients to predict if they will have a stroke
- Important Features:
 - Age
 - Smoker or Non-Smoker
 - Hypertension
 - Blood-Glucose Levels
 - Marital Status
 - Place of Residence
 - Area of Work

Probability of Strokes with Age

Relationship Between Hypertension and Strokes

How did the model do?

- Did well with predicting true negatives
- Was not able to correctly predict any true positives
 - This could be an issue when it comes to predicting strokes
 - The model will most likely predict that you won't have a stroke, even if you will
- Unbalanced dataset
 - There were many more people who didn't have strokes than those who did

Recommendations

- I would not recommend the use of this model
- It will not accurately predict if a patient is likely to have a stroke, which could be deadly
- Moving forward, I will use techniques to balance the data so that the prediction is more accurate
- Doctors should closely monitor patients who have hypertension and/or are over 60 years of age
